Plant Population and Stem Counts to Predict Yield of Modern Alfalfa Varieties

Craig Sheaffer, Krishona Martinson, Jacob Jungers, University of Minnesota

To determine the relationship of alfalfa plant population density and stem density with forage yield of modern alfalfa varieties.

OBJECTIVES

To determine the relationship of alfalfa plant population density and stem density with forage yield of modern alfalfa varieties.

STUDY DESCRIPTION

Plot layout:
Randomized complete block design with four replications.

Locations:
3 locations in Minnesota.

Plant populations:
6, 12, 18, 24, 36, 48, 72 plants per ft².

Alfalfa varieties:
SW5511, SW5509, 5RVR08, and 54VR10.

Analysis:
Alfalfa plant population per ft², stem density per ft², and forage yield were measured from two harvest in the seeding year, and at one harvest in the spring of the year following seeding.

RESULTS

• In the seeding year, by adjusting our seeding rates we achieved a range of plant populations per ft². Varieties did not consistently differ in populations. However, over the season we were challenged to maintain the highest plant populations due to natural thinning of plants.

• In the seeding year, there was no consistent association over locations between plant populations/ft² with forage yields or stem number/ft² with forage yield. While a 6 plants/ft² population had the lowest stem numbers and yields at Rosemount and Becker, differences in stem numbers and yield among the other plant populations were not consistent. Therefore, we could not determine a threshold plant population or stem number that was critical for the seeding year.

• At the first harvest in the spring of the year following seeding, there was a strong association between alfalfa plant populations/ft² and alfalfa stems/ft². The correlation explained over 90% of the variation in the two variables. Stem numbers range from 50 to 80/ft² while plant populations ranged from 6 to over 30/ft². Alfalfa varieties had similar relationships between plant populations and stem densities.

• We observed a significant overwintering loss in alfalfa plant density at the higher seeding rates. While we observed over 60 plants/ft² in the fall of the seeding year at all locations, by spring the highest populations were about 30 plants/ft².

• Responses of yield to plant population/ft² and stem densities/ft² varied among locations. At St. Paul, where we observed the widest range of plant populations, there was a curvilinear relationship between plant populations and stem density with forage yields. Plant population of about 15 plants/ft² or above were required for maximum yields while stem counts of about 67 stems/ft² or above were required. At Rosemount, where there was little change in yield over the range in plant populations and stem counts, forage yield were greatest at plant densities of 27–31 plants/ft² with stem densities near 71–76 stems/ft². At Becker, the response to increasing seeding rates was linear meaning that maximum yields would be achieved at populations greater than 30 plants and stems numbers greater than 70 stems/ft².

Figure 1. The relationship between stems/ft² to forage yield at the first harvest in 2020 at St. Paul, MN.

\[
y = -0.0151x^2 + 0.2631x + 0.7277
\]

\[R^2 = 0.9497\]
CONCLUSIONS/SUGGESTIONS

- Based on results from the seeding year, we concur with Undersander and Cosgrove (2007) who recommended that new seedings should have at least 25 to 30 plants/ft². In our trials, these plant populations provided yields that were not consistently different from populations as high as 72 plants/ft².

- Our results from a single harvest in the year following seeding contrast with existing recommendation in that we found greatest first harvest yields with stem densities of about 70 stems/ft² or greater. Alfalfa populations above 55 stems/ft² have been considered optimum for alfalfa yields with yields declining with decreased stem densities (Undersander and Cosgrove, 2007).

- These results should be considered preliminary and the research is being continued with additional harvests in 2020 and 2021.
